1 Introduction

This document aims at providing a synthetic report on the behaviour of the radiometer in terms of instrumental characteristics and product performances as well as on the main events which occurred during cycle 22.

This document is split in the following sections:

- ❖ Section 2 gives an overview on the status of the current cycle
- ❖ Section 3 addresses the monitoring of the MWR of the current cycle. This section covers the short term monitoring of internal calibration, brightness temperatures and geophysical parameters.
- ❖ Section 4 addresses the long term monitoring from the beginning of the mission. It provides a view of the internal calibration monitoring as well as two subsections covering the monitoring of vicarious calibration targets and geophysical parameters.

2 Overview of Cycle 022

2.1 Status

The Table 1 gives a summary of the instrument behavior during this period.

Parameter	Status	Comments
Instrument		Nominal
Internal Calibration		Nominal
Geophysical products		Nominal
Long-term monitoring		Nominal for three analyses

Table 1 : General overview of the MWR quality assessment

3 MWR Monitoring over Cycle 022

This section is dedicated to the functional verification of the MWR sensor behaviour during cycle 22 (03 September 2017 – 30 September 2017) . The main relevant of the parameters, monitored daily by the MPC team, are presented here.

3.1 Operating modes

The radiometer has several operating modes listed hereafter:

- ❖ Mode 0 : Intermonitoring (Earth observation)
- ❖ Mode 1 : Monitoring
- ❖ Mode 2 : Noise Injection calibration
- ❖ Mode 3 : Dicke Non-Balanced calibration (100% injection – hot point)
- ❖ Mode 4 : Dicke Non-Balanced calibration (50% injection – cold point)

Figure 1 gives the distribution of the different modes in the data.

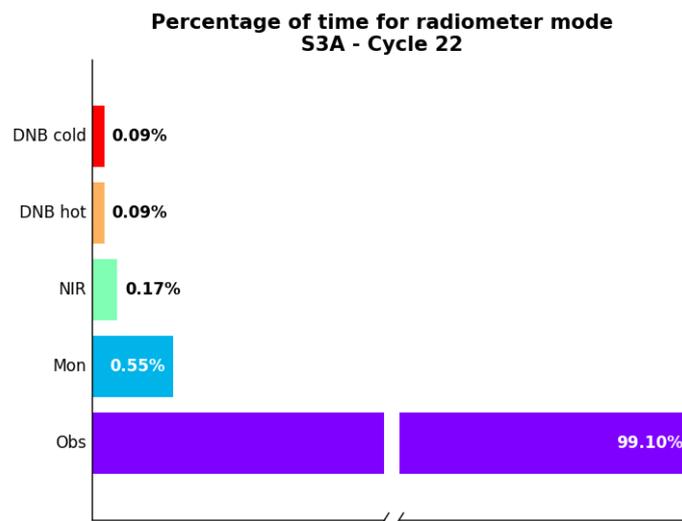

Figure 1 : Distribution of operating mode

For measurements in the Intermonitoring mode, two kind of processing can be used according to the measured brightness temperature. If this temperature is smaller than the reference load inside the instrument, the NIR processing is used; if the temperature is greater, the DNB processing is used. The transition from one processing to the other will occur more or less close to the coast depending on the

internal temperature of the MWR. The internal temperature of the MWR is such that only a small percentage of measurements required a DNB processing in this cycle as shown by Figure 2.

This figure shows also the passage over the US KREMS radar facility in the Kwajalein atoll (9°23'47" N - 167°28'50" E) in the Pacific. For safety reasons, the MWR is switched to a specific mode about 50 km before the facility location and back to nominal mode 50km after.

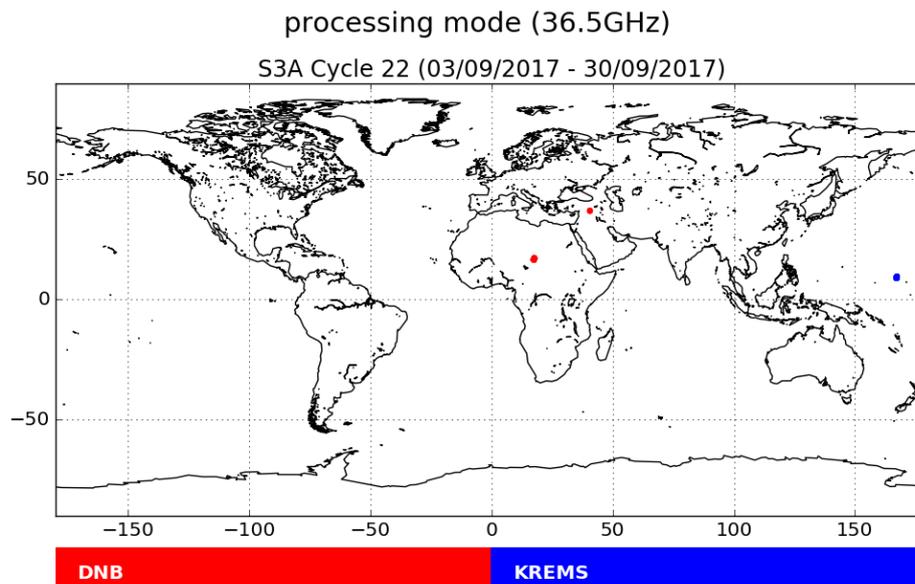

Figure 2 : Map of measurements with DNB processing for 36.5GHz channel (red) and safety mode for both channels over KREMS (blue)

3.2 Calibration parameters

To monitor the instrument behavior during its lifetime, the relevant parameters of the MWR internal in-flight calibration procedure are presented in the following subsections. These parameters are:

- ❖ the gain : this parameter is estimated using the two types of Dicke Non-Balanced calibration measurements (100% and 50% of injection). The DNB processing of the Earth measurements uses this parameter.
- ❖ the noise injection temperature : this parameter is measured during the Noise Injection calibration measurements. The NIR processing of the Earth measurements uses this parameter.

Data used for the diagnosis presented here are data generated by PDGS at Svalbard core ground station.

3.2.1 Gain

Figure 3 shows the monitoring of the receiver gain for the current cycle. The mean value over the cycle is 4.761mV/K and 4.549mV/K for channel 23.8GHz and 36.5GHz respectively. These values are close to values estimated on-ground during characterization of the instrument (4.793mV/K and 4.665mV/K for channels 23.8GHz and 36.5GHz respectively). The gain is relatively stable along this cycle for 23.8GHz channel and shows a small decrease of about 0.005mV/K for 36.5GHz channel. Nominal behavior is observed since only 1 cycle of data is considered in this section. MPC did not receive all data for this cycle which explains the gaps in the timeseries.

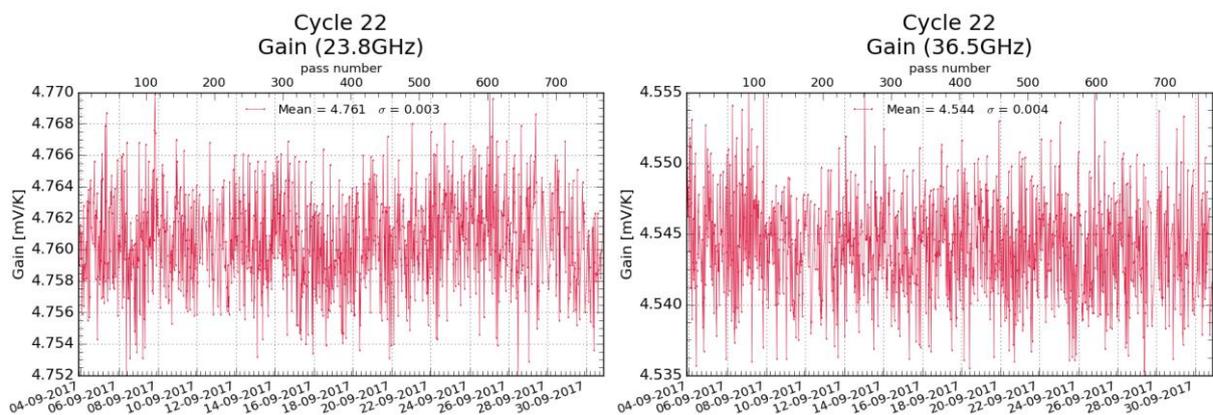

Figure 3 : monitoring of receiver gain for both channels :23.8GHz (left) and 36.5GHz (right)

3.2.2 Noise Injection Temperature

Figure 4 shows the monitoring of the noise injection temperature for the current cycle. The noise injection temperature is constant over the cycle for both channels close to 314K and 288.3 for 23.8GHz and 36.5GHz channels respectively. Nominal behavior is observed since only 1 cycle of data is considered in this section. MPC did not receive all data for this cycle which explains the gaps in the timeseries.

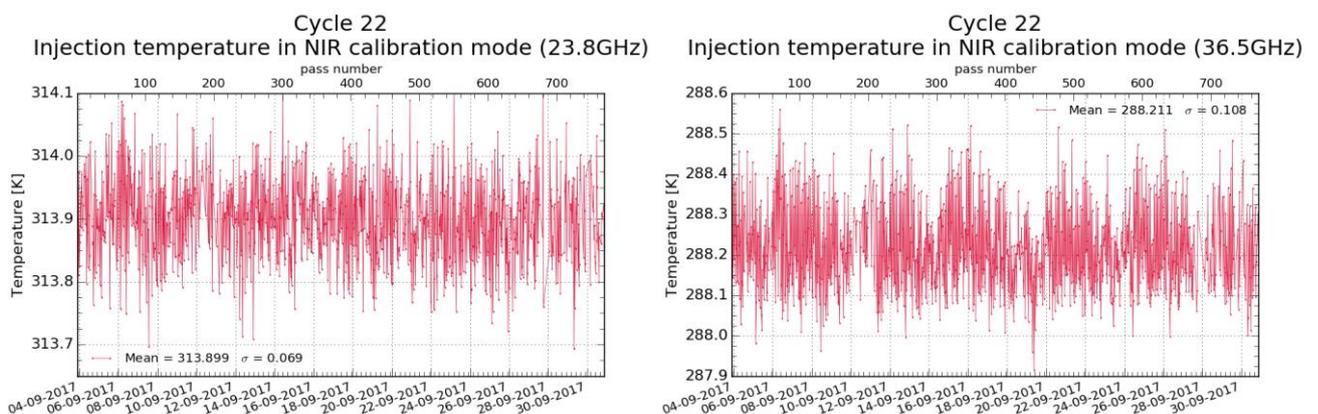

Figure 4 : Monitoring of Noise Injection temperature for both channels :23.8GHz (left) and 36.5GHz (right)

3.3 Brightness Temperatures

Data used for the diagnosis presented here are data generated at Land Surface Topography Mission Processing and Archiving Centre [LN3].

The two following figures show maps of brightness temperatures for both channels split by ascending (right part) and descending (left part) passes. Figure 5 and Figure 6 concern the channels 23.8GHz and 36.5GHz respectively. These maps show a good contrast between ocean and land for both channels. MPC did not receive all data for this cycle which explains the missing passes in the maps.

Figure 5 : Map of Brightness temperatures of channel 23.8GHz for ascending (right) and descending (left) passes

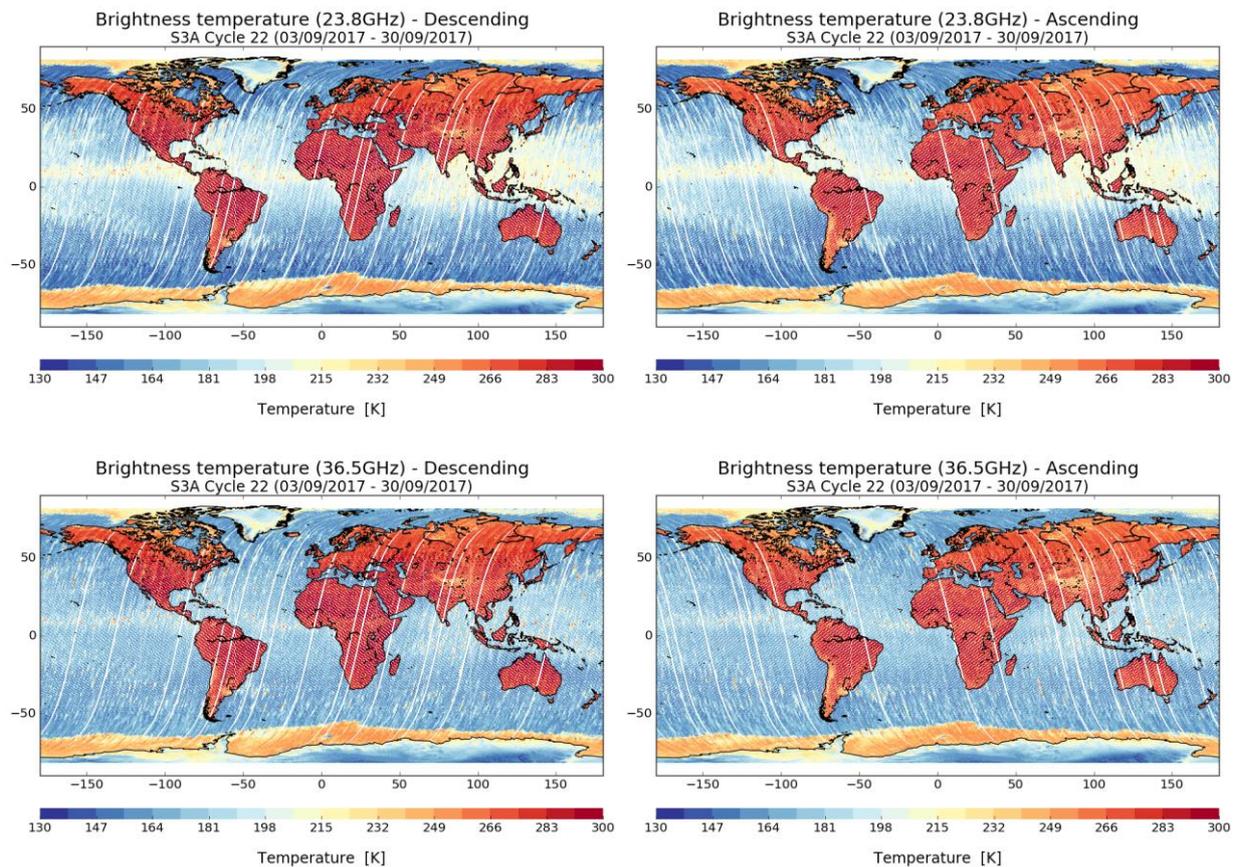

Figure 6 : Map of Brightness temperatures of channel 36.5GHz for ascending (right) and descending (left) passes

--	---	---

3.4 Geophysical products monitoring

The inversion algorithms allow to retrieve the geophysical products from the measurements of the radiometer (brightness temperatures measured at two different frequencies) and the altimeter (backscattering coefficient ie σ_0). Four geophysical products are issued from the retrieval algorithms: the wet tropospheric correction, the atmospheric attenuation of the σ_0 , the water vapor content, the cloud liquid water content. This section provides an assessment of two of these retrievals used by the SRAL/MWR L2 processing: the wet tropospheric correction and the atmospheric attenuation of the σ_0 . The wet tropospheric correction is analysed through the MWR-ECMWF difference of this correction.

3.4.1 Wet Tropospheric Correction

Figure 7 presents the histograms of the MWR-ECMWF differences of wet tropospheric correction (ΔWTC) for cycle 20. In this figure, Sentinel-3A/MWR correction is compared to the correction retrieved by Jason2/AMR (IGDR) and SARAL/MWR (IGDR) over the same period.

The standard deviation of the difference MWR-ECMWF corrections for S-3A is around 1.37cm for both SAR and PLRM corrections while it is 1.54cm for SARAL and 1.15cm for Jason-3. First Jason-3 benefits from its three channels radiometer (18.7GHz, 23.8GHz, 34GHz), providing a correction with a smaller deviation with respect to the model. SARAL/MWR is closer to S3-A/MWR in this context with its two channels (23.8GHZ and 37GHZ for SARAL, 23.8 and 36.5GHz for S3-A). Then the standard deviation for SARAL is the closest reference, even though the σ_0 in Ka band raises some questions. With the use of STC products for S3-A, the ΔWTC for the three instruments are directly comparable since all use ECMWF analyses for the computation of the model correction. The standard deviation of ΔWTC for S3-A is smaller than for SARAL meaning that we have a better estimation of the correction for S3-A according to these metrics. Jason-3 gives the best performances with the smallest deviation. Moreover, one can notice that both SAR and PLMR corrections have very similar performances: mean(std) of ΔWTC being close to 0.23cm(1.37cm) and 0.24cm(1.35cm) for SAR and PLRM respectively.

Figure 8 presents a map of the ΔWTC for Sentinel3-A only for SAR correction on the left and PLRM correction on the right. For this cycle, the maps show geographical patterns expected for this parameter. Note that the color scale is centered to the mean value. The comparison with Jason2 map of ΔWTC (Figure 9) shows similarities although Sentinel-3A ΔWTC is larger than Jason2 because of their different instrument configuration.

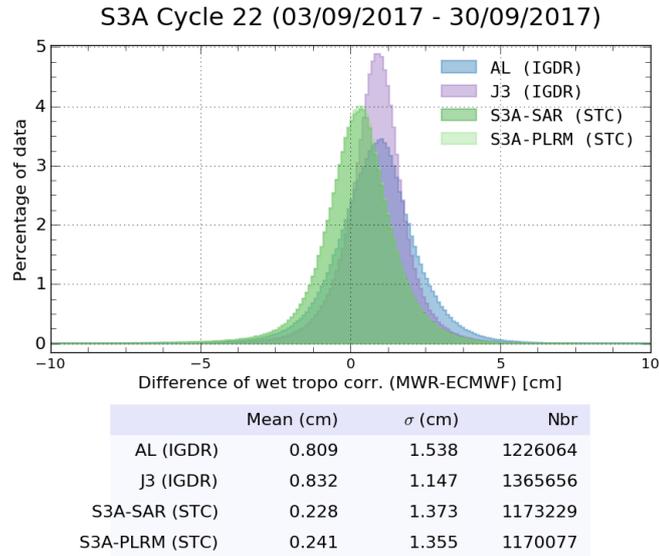

Figure 7: Histograms of MWR-ECMWF difference of wet tropospheric correction for SARAL/MWR, Jason3/AMR and Sentinel-3A/MWR SAR and PLRM

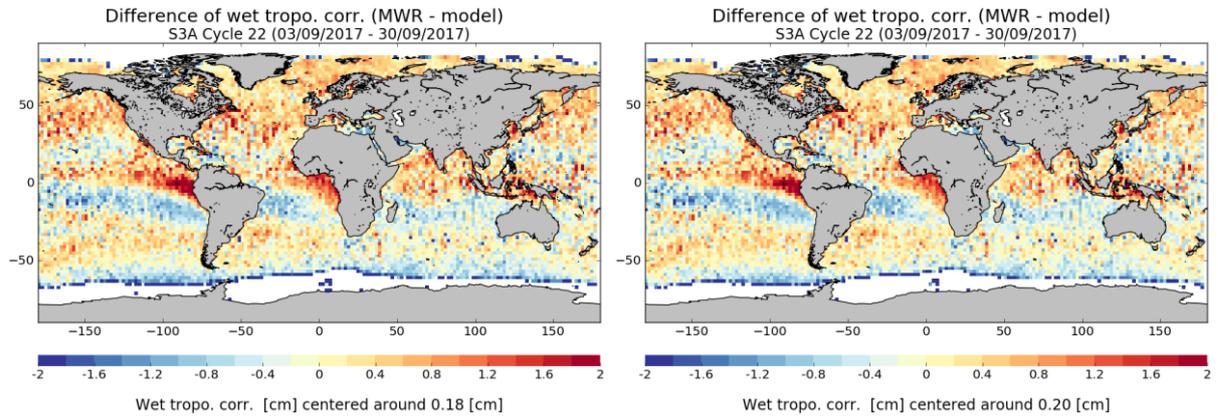

Figure 8 : MWR-ECMWF difference of wet tropospheric correction : using SAR (left) and PLRM altimeter backscatter (right)

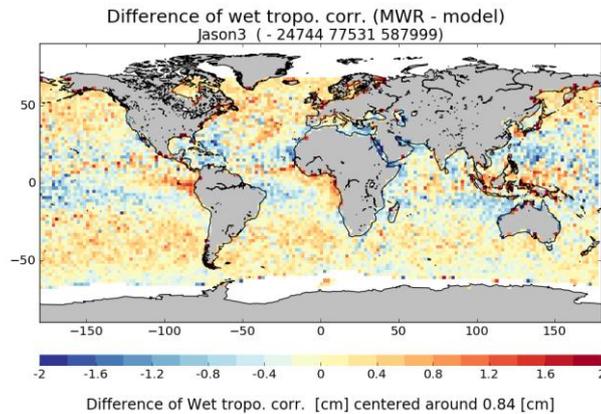

Figure 9 : Jason3/AMR MWR-ECMWF difference of wet tropospheric correction (IGDR product)

3.4.2 Atmospheric Attenuation

The left part of Figure 10 presents the histograms of the Ku band atmospheric attenuation of the Sigma0. In this figure, Sentinel3-A attenuation is compared to the model attenuation computed from ECMWF analyses and Jason-3 attenuation from IGDR products. The results for both instruments are very similar to model results with an average attenuation close to 0.21dB for S3-A , 0.2dB for Jason3 (0.2dB for model attenuation) . The right part of Figure 10 shows a map of the difference of MWR attenuation and model attenuation computed from ECMWF analyses for Sentinel3-A. Globally a bias of 0.01 dB between MWR and model attenuation can be estimated from this plot.

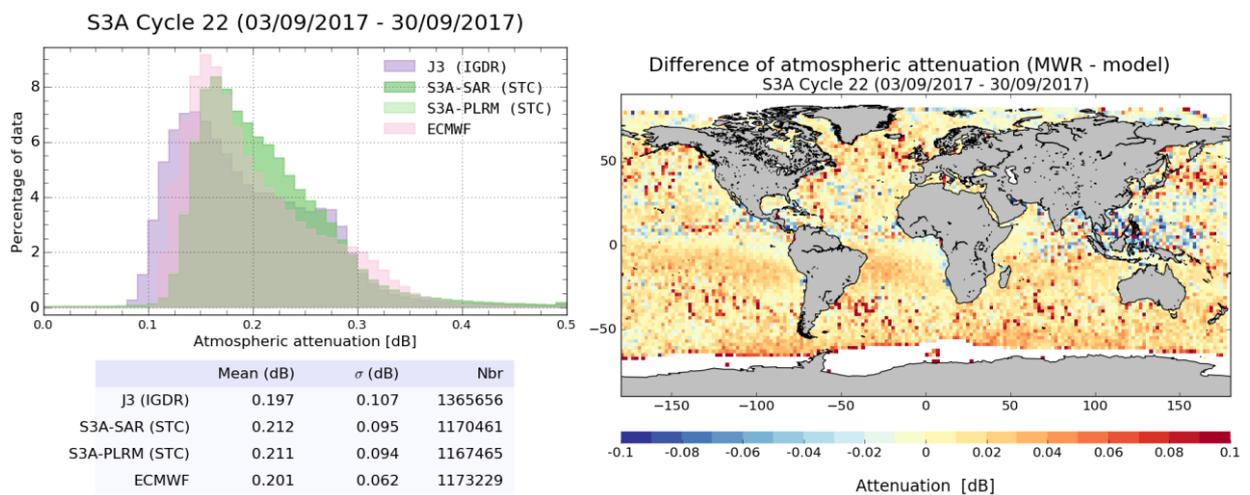

Figure 10 : Ku band Atmospheric attenuation of the Sigma0
Left : Histograms for Sentinel-3A/MWR, Jason3/AMR, Model attenuation; Right: Map of difference of MWR-model atmospheric attenuation for Sentinel-3A

4 Long-term monitoring

In this section, a long-term monitoring of the MWR behaviour is presented.

4.1 Internal Calibration parameters

This section presents a long term monitoring of internal calibration parameters. Data used for the diagnosis presented here are:

- ❖ Reprocessed data (processing baseline 2.15) from cycle 1 to cycle 16
- ❖ MWR L1B data generated by PDGS at Svalbard core ground station are used from 26/10/2016

4.1.1 Gain

Figure 11 shows the daily mean of the receiver gain for both channels. This calibration parameter is used in the DNB processing of the measurements. As seen previously in section 3.1, only a small part of the measurements are processed in DNB mode. The first part of the monitoring of the calibration parameters shown here is performed with products generated during the reprocessing of processing baseline 2.15, the second part using NRT products from the day of the IPF update on the Svalbard ground station forward.

From the two panels of Figure 11, one can see that the receiver gain has a different behaviour for each channel. The gain for the 23.8GHz is slowly increasing since the beginning of the mission showing an four slopes and three inflexion points at August 2016, Februray 2017 and June 2017. The gain has increased of +0.03mv/K since the beginning of the mission. For the 36.5GHz channel, the gain is increasing from cycle 1 and then starts to decrease at the beginning of cycle 4. During cycle 15, it started to increase again, and decrease since cycle 18. Due to the small number of data processed using this parameter, it will be difficult to assess if this decrease has an impact on data quality. The monitoring will be pursued and data checked for any impact.

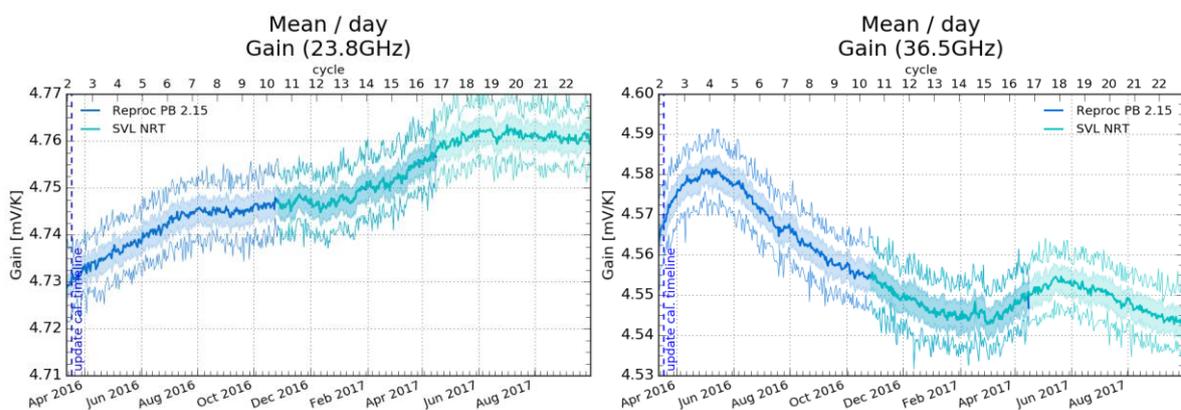

Figure 11 : Daily mean of the gain for both channels : 23.8GHz (left) and 36.5GHz (right)

4.1.2 Noise Injection temperature

Figure 12 shows the daily mean of the noise injection temperature for both channels. This calibration parameter is used in the NIR processing of the measurements. As seen previously in section 3.1, the main part of the measurements are processed in NIR mode. Moreover the first part of the monitoring of the calibration parameters is performed using products generated during the reprocessing or processing baseline 2.15, the second part using NRT calibration products from the day of the IPF update on the ground station.

From the two panels of Figure 12, one can see that the noise injection parameter has a different behaviour for each channel. For the 23.8GHz channel, the noise injection temperature has decreased of 0.5K during the first 2 cycles, after what there has been no significant change of behaviour until cycle 13. During this cycle, the noise injection temperature seems to start a slow decrease. For the channel 36.5GHz, one can see that the injection temperature is not stable : it increased from cycle 1 to 5 followed by a stabilization period from beginning of June (cycle 5) to mid-July (end of cycle 6) when it starts to decrease, then increase since cycle 14 until cycle 19. The monitoring will be pursued and data checked for any impact.

Some peak values are noticeable at the end of cycle 4 (mainly channel 23.8GHz), at the end of cycle 6, during cycle 9, 10, 12 and 16. Some of these peaks concerns both channels at the same time, while a small part of them only one of them. The investigations performed in the cycle 6 report has shown that these measurements are localized around a band of latitude that may change along the time series. The source is not yet clearly identified but a intrusion of the Moon in the sky horn is suspected.

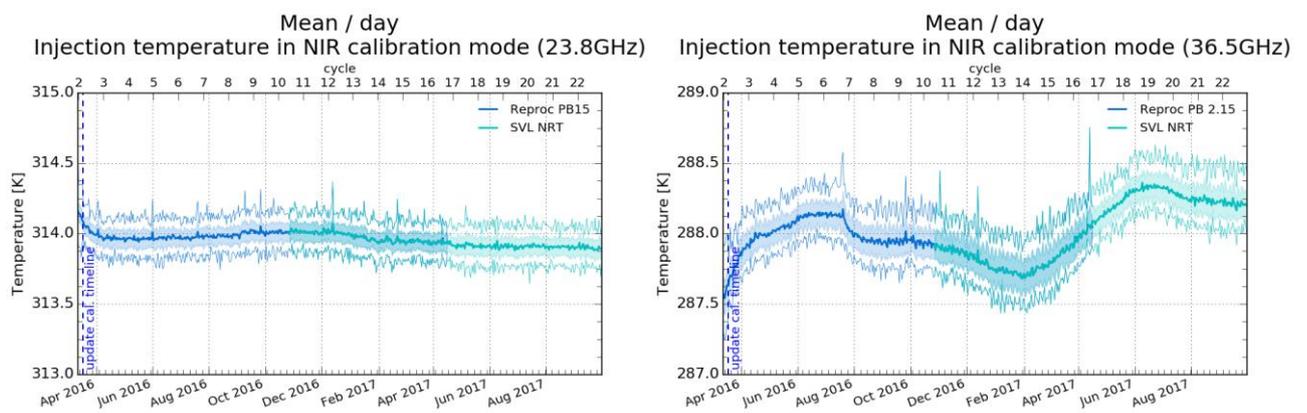

Figure 12 : Daily statistics of the noise injection temperature for channel 23.8GHz (left) and 36.5GHz (right): mean (bold line), min/max (thin line), standard deviation (shade)

--	---	--

4.2 Vicarious calibration

The assessment of the brightness temperatures quality and stability is performed by the use of vicarious calibrations. Two specific areas are selected. Sentinel-3A data used in this section are:

- ❖ Coldest ocean temperature analysis uses Level 2 data
 - data from processing baseline 2.15 reprocessing from June 2016 to April 2017.
 - STC Marine data since December 2016
- ❖ Amazon forest analysis uses Level 1B data:
 - data from processing baseline 2.15 reprocessing from June 2016 to April 2017.
 - STC Land data from LN3 processing center

4.2.1 Coldest ocean temperatures

The first area is the ocean and more precisely the coldest temperature over ocean. Following the method proposed by Ruf [RD 1], updated by Eymar [RD 3] and implemented in [RD 7], the coldest ocean temperatures is computed by a statistic selection. Ruf has demonstrated how a statistical selection of the coldest BT over ocean allows detecting and monitoring drifts. It is also commonly used for long-term monitoring or cross-calibration [RD 4] [RD 5] [RD 6].

The Figure 13 presents the coldest ocean temperature computed following method previously described at 23.8GHz channel for Sentinel-3A/WMR and three other microwave radiometers: AltiKa/MWR, Jason2/Jason3/AMR and Metop-A/AMSU-A. For AMSU-A, the two pixels of smallest incidence (closest to nadir) are averaged. The Figure 14 presents the same results for the liquid water channel of the same four instruments: 36.5GHz for Sentinel-3A, 37GHz for AltiKa , 34GHz for Jason2/Jason3 and 31.4GHz for Metop-A.

Concerning the 23.8GHz channel presented on Figure 12, one can see the impact of the calibration of the MWR with the increase of the coldest ocean brightness temperature: around 135K before and 140K after the update of the characterisation file and LTM files for the STC on the fly products (green line). The temperature of the coldest ocean points is now closer to the other sun-synchronous missions (Metop-A, SARAL/AltiKa). The light green line is for the reprocessed data of processing baseline 2.15 that is with the same configuration than the on-the-fly products after January. One can notice the very good agreement between on the overlapping period.

The analysis for the liquid water channel (Figure 14) is more complicated due to the different frequency used by these instruments for this channel: 36.5GHz for Sentinel-3A, 37GHz for AltiKa, 34GHz for Jason2/Jason3 and 31.4Ghz for AMSU-A. But the coldest temperature can be used relatively one with another. For instance, one can see that the difference between AltiKa and Jason-2/Jason3 is about 6K

which is in line with the theoretical value estimated by Brown between the channel 34 GHz of JMR and the channel 37 GHz of TMR ($-5.61 \text{ K} \pm 0.23 \text{ K}$) [RD 8]. Then we can expect that Sentinel3 should be closer to AltiKa than Jason2 due to the measurement frequency. The STC and NTC products reprocessed using the new MWR characterisation file (light green curves) show hottest temperatures similar to AltiKa. For the on-the-fly STC products, a jump in the temperatures occurs with the update of MWR characterisation file.

The period is too short to allow a drift analysis but it is reassuring to see that Sentinel-3A/MWR has the same behaviour than the other radiometer.

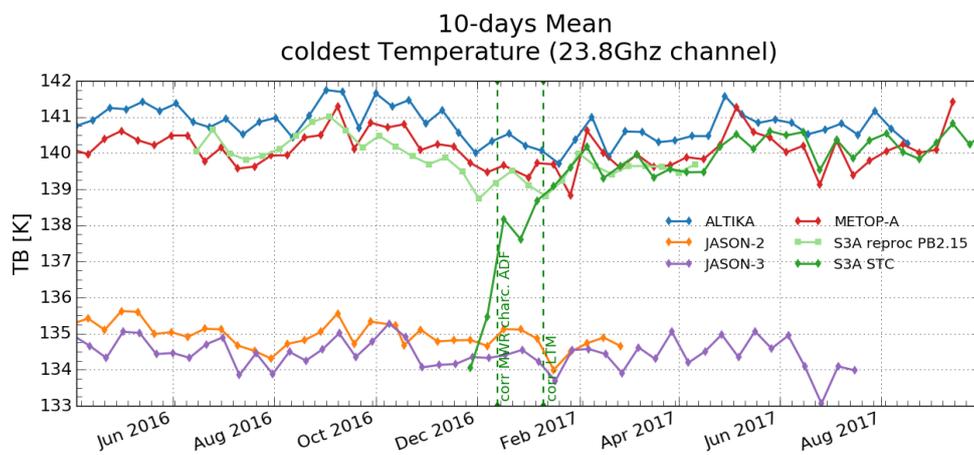

Figure 13 : Coldest temperature over ocean at 23.8GHz for Sentinel-3A, SARAL/AltiKa, Jason2, Jason3 and Metop-A/AMSU-A

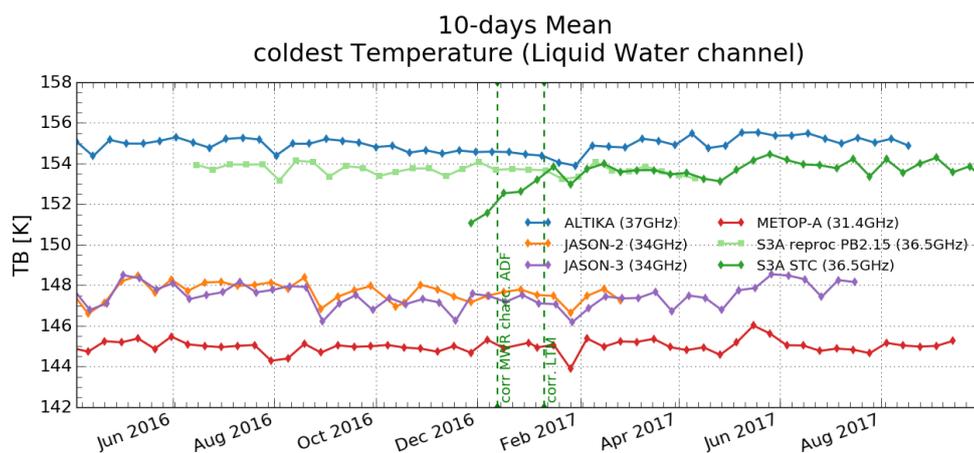

Figure 14 : Coldest temperature over ocean for the liquid water channel Sentinel-3A, SARAL/AltiKa, Jason2, Jason3 and Metop-A/AMSU-A

4.2.2 Amazon forest

The second area is the Amazon forest which is the natural body the closest to a black body for microwave radiometry. Thus it is commonly used to assess the calibration of microwave radiometers [RD 2][RD 3]. The method proposed in these papers have been used as a baseline to propose a new method implemented in [RD 7]. In this new approach, a mask is derived from the evergreen forest class of GlobCover classification over Amazon. The average temperature is computed here over a period of 10 days except for Jason2/Jason3 for which a period of one month is required. Due to the orbit of Jason2, a longer period is required to reach a significant number of measurements falling within the mask.

The averaged temperature over the Amazon forest is shown on Figure 15 and Figure 16 for water vapor channel (23.8GHz) and liquid water channel respectively. These two figures show the very good consistency of Sentinel-3A with the three other radiometers on the hottest temperatures: around 286K for the first channel, and 284K for the second channel. The mean value as well as the annual cycle is well respected. These results show the correct calibration for the hottest temperatures and the small impact of the MWR calibration for the hottest temperatures when comparing the reprocessed data using processing baseline 2.15 (light green line) and the on-the-fly products, here STC L1B products . As for the coldest ocean temperatures, the period is too short to allow a drift analysis.

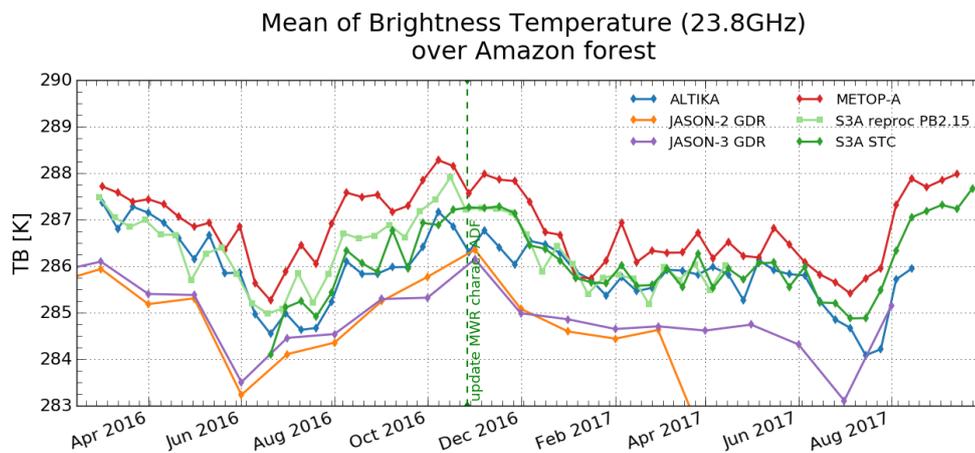

Figure 15 : Average temperature over Amazon forest at 23.8GHz channel for Sentinel-3A, SARAL/AltiKa, Jason2, Jason3, and Metop-A/AMSU-A

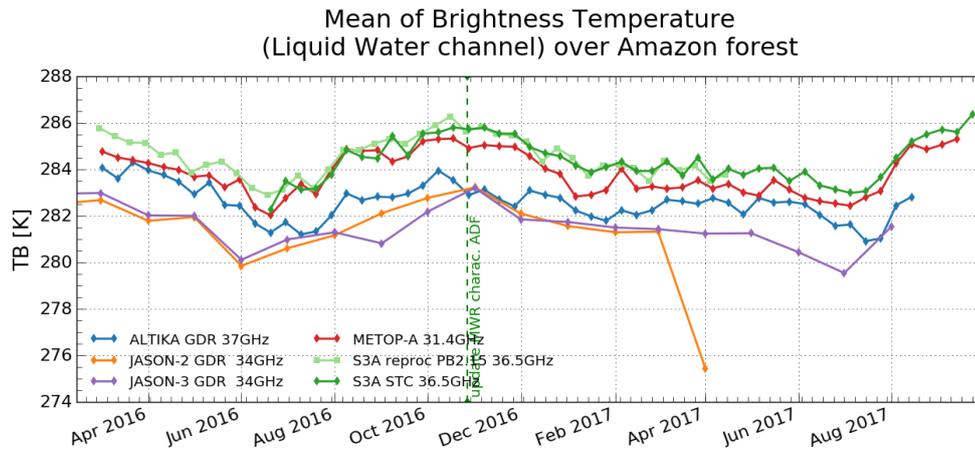

Figure 16 : Average temperature over Amazon forest at 36.5GHz channel for Sentinel-3A, SARAL/AltiKa, Jason2, Jason3 and Metop-A/AMSU-A

4.3 Geophysical products

4.3.1 Monitoring of geophysical products

In this section, comparisons of MWR-model fields are performed for several instruments. The selected instruments are Jason2/Jason3/AMR and SARAL/ALtiKa. For a long term monitoring perspective, GDR products are used to compute the difference with respect to model values. Model values for each field are computed using ECMWF analyses data. GDR products for each mission have their own latency due to cycle curation and mission constraints such as the cold-sky calibration for Jason2 and Jason3 missions. Indeed, ALtiKa GDR is available with delay of ~35 days, while for Jason2 or Jason3 this delay is up to 60 days.

4.3.1.1 Wet tropospheric correction

Figure 17 shows the monitoring of the MWR-model differences of wet tropospheric correction (Δ WTC) using Level2 STC products from the Marine Center. Sentinel-3A correction is compared to Jason2/AMR, Jason3/AMR and SARAL/MWR corrections. For SARAL (annoted AL in Figure 17), Jason2 (J2) and Jason3 (J3), GDR products were selected. The daily average of Δ WTC for Sentinel-3A is close to 0cm since 10th of January while it is around 0.6cm for SARAL and Jason2. This difference is small and results partially from the inversion algorithm.

The more relevant parameter to assess the performance of a correction is the standard deviation of Δ WTC. First Jason-2 and Jason3 benefit from their three channels radiometer (18.7GHz, 23.8GHz, 34GHz), providing a correction with a smaller deviation with respect to the model. SARAL/MWR is closer to S-3A/MWR in this context with its two channels (23.8GHZ, 37GHz). Then the standard deviation for SARAL is the closest reference, even though the Sigma0 in Ka band raises some questions. With the use of STC products for S-3A, the Δ WTC for the three instruments are directly comparable since all missions use ECMWF analyses for the computation of the model correction. The standard deviation of Δ WTC for S-3A is smaller than for SARAL meaning that we have a better estimation of the correction for S-3A according to these metrics. Jason2 and Jason3 give the best performances with the smallest deviation. Moreover, one can notice that both SAR and PLMR corrections have very similar performances. The peak value in the standard deviation observed during cycle 14 for both SAR and PLRM Δ WTC comes from the model correction provided by the products. During this day, one ECMWF analyse over the four required for a good estimation all along the day was missing.

An ECMWF model change occurred the 11th July induces a 1 mm bias on the mean value of the PLRM and SAR Δ WTC for Sentinel-3A as well as for SARAL Δ WTC (AL).

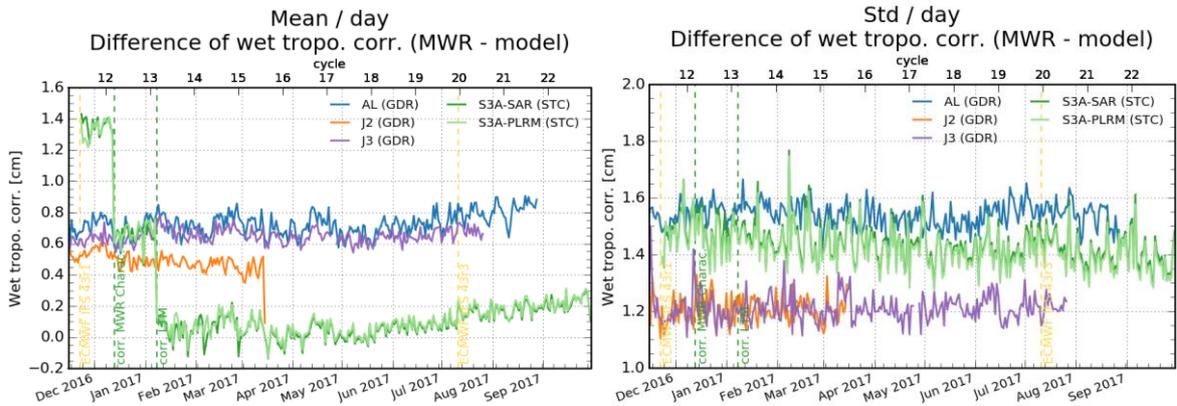

Figure 17 : Monitoring of difference MWR-ECMWF correction : daily average (left) and standard deviation (right)

4.3.1.2 Atmospheric attenuation

Figure 18 shows the monitoring of the MWR-model differences of atmospheric attenuation ($\Delta\text{ATM_ATT}$) using Level2 STC products from the Marine Center. Sentinel-3A correction in Ku band is compared to Jason2/AMR and Jason3/AMR. SARAL/AltiKa is not shown here because the altimeter uses the Ka band. Figure 18 shows that the several evolutions affected mainly the average value of $\Delta\text{ATM_ATT}$: the daily average show steps when the configuration of the IPF is updated, while the standard deviation is stable over the whole period. The mean of $\Delta\text{ATM_ATT}$ for Jason2 and Jason-3 is around 0.005dB, a little larger for S-3A: around 0.015dB since mid-January, more stable around 0.01dB since July. A finer tuning of the retrieval algorithm is expected to correct for this small difference.

No impact of the last ECMWF model change that occurred the 11th July can be noticed on the atmospheric attenuation for Sentinel-3A. Values for other missions were under processing or GDR products not yet available at the time of writing this report.

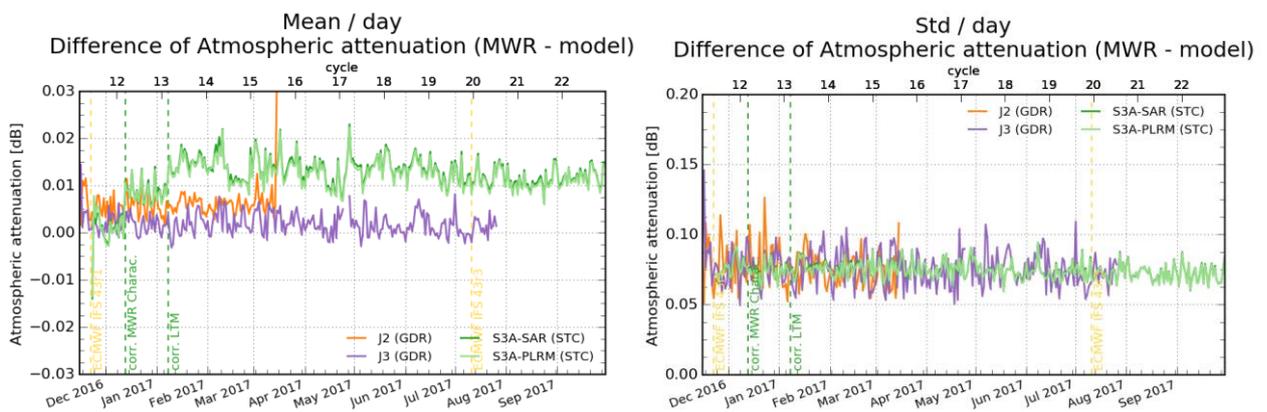

Figure 18 : Monitoring of difference MWR-model atmospheric attenuation : daily average (left) and standard deviation (right)

4.3.1.3 Water vapor content

Figure 19 shows the monitoring of the MWR-model differences of atmospheric attenuation (ΔWV) using Level2 STC products from the Marine Center. Sentinel-3A correction is compared to Jason2/AMR and Jason3/AMR. Figure 19 shows that the several evolutions affected mainly the average value of ΔWV : the daily average show steps when the configuration of the IPF is updated, while the standard deviation is stable over the whole period. The mean of ΔWV for Jason2 is between -1.0kg/m^2 and -0.5kg/m^2 , very close to AltiKa results of -0.5kg/m^2 , around -1.0kg/m^2 for Jason3, and a little larger for Sentinel-3A: around 0.5kg/m^2 since mid-January. The standard deviation of ΔWV is very similar between AltiKa and S-3A between 2 and 2.5kg/m^2 , and a little smaller for Jason2 and Jason3 around 2kg/m^2 . A finer tuning of the retrieval algorithm is expected to correct for the small difference of the daily average.

The ECMWF model change of the 11th July induces a bias of 0.25kg/m^2 on the mean value of ΔWV for Sentinel-3A. It seems that SARAL show the same bias on ΔWV , to be confirmed with a longer timeseries. Values for other missions were under processing or GDR products not yet available at the time of writing this report.

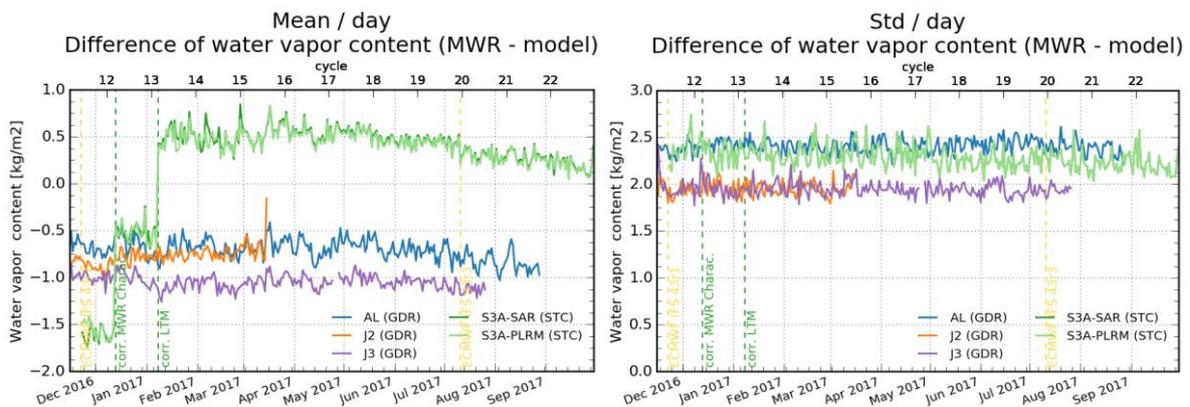

Figure 19 : Monitoring of difference MWR-ECMWF water vapour content : daily average (left) and standard deviation (right)

4.3.1.4 Cloud liquid water content

Figure 20 shows the monitoring of the MWR-model differences of cloud liquid water content (ΔWC) using Level2 STC products from the Marine Center. Sentinel3-A fields is compared to Jason2/AMR, Jason3/AMR and SARAL/AltiKa. Figure 20 shows that the several evolutions affected mainly the average value of ΔWC : the daily average show steps when the configuration of the IPF is updated but with a smaller effect than for the other geophysical parameters, while the standard deviation is stable over the whole period. The mean of ΔWC is close to 0.04kg/m^2 for AltiKA, Jason2 and S3-A but around

0.02kg/m² for Jason3. The standard deviation of Sentinel-3A is little higher than for the three other missions: ~0.3kg/m² for S3-A, 0.2 kg/m² for the other missions. This point needs to be analyzed.

No impact of the last ECMWF model change that occurred the 11th July can be noticed on the cloud liquid water content for Sentinel-3A. Values for other missions were under processing or GDR products not yet available at the time of writing this report.

4.3.2 Comparison to in-situ measurements

The comparison of wet tropospheric correction to Radiosonde measurements will be addressed with 2 years of data.
