### 2 SRAL Internal Calibration Monitoring.

### 2.1 Introduction

The SRAL instrumental calibration is assessed during the mission. Several parameters are monitored and analysed in detail in order to characterise the altimeter performance along the mission lifetime.

Two main groups of calibration parameters are monitored.

The first is derived from the Point Target Response (PTR) calibration in CAL1 mode. The PTR signal follows the same circuitry path as the science waveforms within the calibration loop. The delay caused by the travel through the calibration path can be measured and afterwards compensated in the total range computation. The attenuation suffered by the signal when traveling through the instrument also needs to be monitored and the science waveforms need to be compensated for this power variations. Moreover, there are a collection of other parameters to be checked, such as the PTR width and the secondary lobes features. These CAL1 parameters are produced separately for LRM and SAR modes, as they follow different instrumental paths, and also they are duplicated for Ku-band and C-band. Moreover there are different options for characterising the delay and power of the closed loop signal, such as the PTR maximum power or PTR maximum position.

The second is related to the Instrument Transfer Function, measured by the CAL2 mode. The science waveforms spectra is distorted by the on-board instrumental hardware sections. Therefore, in order to retrieve the original echo shape, we need to compensate for this effect. Several parameters are derived from the analysis of the CAL2 waveforms for characterizing it and dissect any feature along the mission lifetime. The CAL2 waveform is the same for both modes LRM and SAR, but there is a distinction between bands Ku and C.

Additionally, for SAR mode, the two intra-burst corrections are monitored: they are the power and phase progressions within a burst. Science pulses within a burst are to be corrected for these expected variations in the burst. Some characteristics are computed for describing and following up their behaviour along the S3 mission.

It is also of major importance the monitoring of the on-board clocks. The altimeter clock counter, responsible for computing the echo travel time, has a multiplicative impact in the range determination. The platform clock is responsible for the overall platform instruments datation. Their stability and performance are to be supervised along the mission.

Finally, the data coming from the thermistors located in the different sections of the on-board HW (HKTM products), are to be analysed in order to check the relation of any calibration parameters anomaly with the thermal behaviour, and find solutions for modelling the instrument characterisation (for instance orbital oscillations) if needed.

An important remark is to be made: although we can see a certain drift of a specific calibration parameter along the mission, this is not to be considered as a warning for the quality of the science

Page: 3

data, as long as the instrumental calibration is correctly applied during the science data processing. A warning shall be raised in the scenario of a calibration parameter value approaching the mission requirement bounds.

### 2.2 Cyclic In-Flight Internal Calibration.

In this chapter, the monitoring of all calibration modes main parameters is depicted in figures. An analysis of the cycle results is developed in chapter 2.3.

#### 2.2.5 On-board Clock Performance

The altimeter USO clock frequency has a major multiplicative impact in the determination of the altimeter range. The USO clock is the one that drives the chirp generation and controls the acquisition time (window delay or tracker range) of the returned echo signal. Here below are depicted the USO frequency long term monitoring (Figure 2-35) and its impact in range (Figure 2-36).

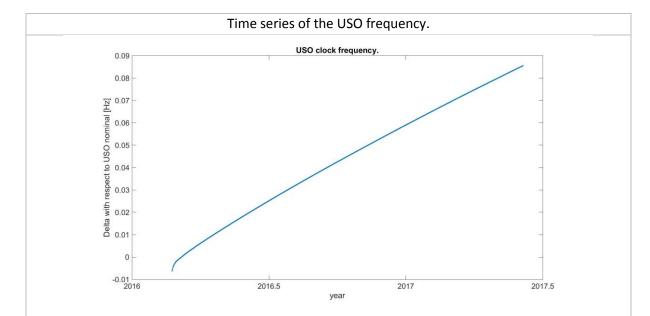

Figure 2-35. USO frequency as in USO Auxiliary File. The results depicted are in Hz and correspond to the Delta with respect to the 10 MHz USO nominal frequency.

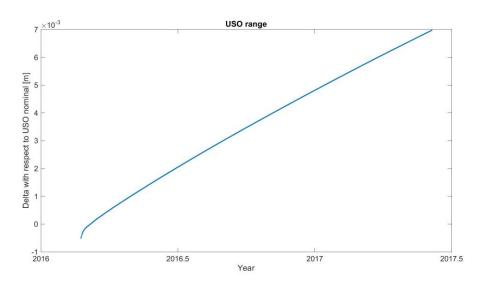

Figure 2-36. USO frequency impact in range, considering a circular orbit at 815 Km over a circular earth (constant echo travel).

### **S3-A SRAL Cyclic Performance Report**

Cycle No. 021

Ref.: S3MPC.ISR.PR.04-021

Issue: 1.0

Date: 07/09/2017

Page: 23

The trend of the altimeter USO clock impact in the range is constant and about 5 mm per year.

The USO impact in the range can change around an orbit considering an elliptical orbit and the variations on the surface elevations, but these changes are far below the nominal absolute values.

Also the temperatures on-board can make the clock to suffer frequency fluctuations, but as we can see in the previous figures, no visible effects of this kind has been observed so far.

The above USO clock performance has been plotted considering a Long Term Monitoring USO Auxiliary File (DELTAF\_MOD field) with date 2017/06/06. When this file is delivered operationally within the S3MPC team platform, updated plots will be included, with cyclic information in this section, and mission series in the next chapter.

### 2.3 Cyclic SRAL Status Summary

This section is dedicated to a summary of the cyclic performances and status of the altimeter parameters exposed in section 2.2.

For the analysed period, none of the calibration parameters is showing a significant anomalous behaviour. Nonetheless some specific observations are explained here below.

As expected, the Ku band (SAR science main band) calibration parameters performances are better than the ones from the C band. The calibration data dispersion is higher for the C band.

In general, the LRM and SAR performances are similar for a given band (Ku or C).

In Table 2-1 the main CAL1 parameters statistics are detailed.

	Ku band		C band			
Calibration Parameter	mean	annual slope	standard deviation	mean	annual slope	standard deviation
LRM CAL1 time delay	1.0070 m	1.84 mm	0.66 mm	0.8930 m	-5.48 mm	2.79 mm
SAR CAL1 time delay	1.0067 m	2.14 mm	0.66 mm	0.8936 m	-5.40 mm	2.80 mm
LRM CAL1 power	57.74 dB	-0.52 dB	0.05 dB	51.43 dB	0.58 dB	0.2
SAR CAL1 power	62.17 dB	-0.54 dB	0.05 dB	48.94 dB	0.59 dB	0.20 dB
LRM CAL1 PTR width	0.4164 m	-5.71 mm	1.22 mm	0.4547 m	-12.28 mm	7.10 mm
SAR CAL1 PTR width	0.4161 m	-5.68 mm	1.22 mm	0.4545 m	-12.36 mm	7.10 mm

Table 2-1. Collection of calibration parameters statistics for all modes and bands covering the cycle period.

The CAL1 power trend for Ku band is no longer close to -1 dB/yr as at the first cycles of the mission (see section 2.4). It follows a decreasing trend, close to 0.6 dB/yr. The CAL1 power trend for C band has been changing its trend sign in the last cycles.

The Ku band CAL1 time delay slope has been changing its trend sign in the last cycles in the order of few mm/year, usually with negative values.

The cycle mean values of the CAL1 width are decreasing over the last cycles, and its cycle inter-annual drift are two orders of magnitude below the nominal PTR width value (Ku-band).

Page: 28

After a L1B IPF code fix on the CAL1 intra-burst corrections, the Burst Power correction noise is highly reduced (from 80 mdB to 0.6 mdB), and the Burst Phase correction is reversed with respect to the previous version. A much more stable value of the burst power slope is now revealed, around 2.55 mdB/pulse.

The thermistors values are showing a stable series over the analysed period.

CAL2 and Autocal parameters are stable.

All these observations are related to the different SRAL calibration parameters during this cycle. A whole mission observation is developed in section 2.4.

## 2.4 Mission SRAL Status Summary

The main L1b calibration parameters series are gathered and plotted in this section, in order to observe their whole mission behaviour. For the sake of simplicity, the C band and the LRM mode have been excluded.

The plotted calibration parameters are:

- CAL1 time delay
- CAL1 power
- PTR width
- Burst corrections (power and phase) and their slopes
- CAL2 waveform ripples shape, plus the waveforms slopes and detrended standard deviations
- Autocal averaged differences and attenuation progression

Also the SAR mode thermistors series is plotted.

Page: 36

So far the only clear and notable drift observed in the whole mission series is in the CAL1 Ku Power series, where we observe a significant power decay. Anyhow, it has decreased the observed trend in the last cycles. In cycles 8, 15 and 21 the whole mission SAR Ku Total Power trend in absolute values was respectively of 0.89, 0.64, and 0.58 dB/year. Hence, we can state a slow stabilisation of this parameter.

## **S3-A SRAL Cyclic Performance Report**

Cycle No. 021

Ref.: S3MPC.ISR.PR.04-021

Issue: 1.0

Date: 07/09/2017

Page: 37

Also the PTR time delay has decreased its negative trend. In cycles 8, 15 and 21 the whole mission SAR Ku Time Delay trend in absolute values was respectively of 1.96, 1.18 and 1.01 mm/year.

The PTR width for the Ku band has a trend around -0.45 mm/year, three orders of magnitude below its absolute value.

The attenuation steps progression in dB is shown in Figure 2-53 and

Figure 2-54, where we can check, for each attenuation step, the delta in attenuation with respect to the previous value in time. The tendencies are visible for specific attenuations in each band case, with small drifts (see colour code at right hand side) of up to 0.04 dB.

In terms of intra-burst corrections, the new L1B code version, implemented during cycle 15, causes a drastic change in the series. A new whole mission CAL L1B reprocessing campaign shall be done to show the new series for both intra-burst corrections without mixing the two versions. Their slopes along the mission are quite stable, except for the burst power correction excursion around decimal year 2017.55 due to a change in the on-board thermal conditions.

The CAL2 parameters behaviour is stable along the mission.

The thermistors data series are generally showing a decreasing slope up to the beginning of 2017, as shown in Figure 2-55 and Figure 2-56. In 2017 it begins a new phase of temperatures increase, stabilised around decimal year 2017.4. In decimal year 2017.55 there is an increase of the thermistors values of around 0.2 °C, returning after several orbits to its precedent values. After 2017.5 a decreasing of the temperatures is observed.

Finally, the collection of statistics for the main calibration parameters is depicted in Table 2-2 for both modes and bands. Once more we observe the better performance (less standard deviation) of the Ku band with respect to the C band, and the general similar values and trends between modes (with some exceptions such as the time delay slope and the power absolute values).

	Ku band			C band			
Calibration Parameter	mean	annual slope	standard deviation	mean	annual slope	standard deviation	
LRM CAL1 time delay	1.0076 m	-1.35 mm	0.80 mm	0.8934 m	-0.73 mm	2.83 mm	
SAR CAL1 time delay	1.0072 m	-1.01 mm	0.73 mm	0.8939 m	-0.57 mm	2.83 mm	
LRM CAL1 power	58.03 dB	-0.56 dB	0.20 dB	51.43 dB	0.02 dB	0.22 dB	
SAR CAL1 power	62.47 dB	-0.58 dB	0.21 dB	48.94 dB	0.02 dB	0.22 dB	

## **S3-A SRAL Cyclic Performance Report**

Cycle No. 021

Ref.: S3MPC.ISR.PR.04-021

Issue: 1.0

Date: 07/09/2017

Page: 38

	Ku band	band			C band		
Calibration Parameter	mean	annual slope	standard deviation	mean	annual slope	standard deviation	
LRM CAL1 PTR width	0.4165 m	-0.43 mm	1.16 mm	0.4547 m	-0.31 mm	6.98 mm	
SAR CAL1 PTR width	0.4163 m	-0.45 mm	1.16 mm	0.4546 m	-0.32 mm	6.98 mm	

Table 2-2. Collection of calibration parameters statistics for all modes and bands covering the whole mission.

The long term drift for the time delay and power variables is higher in absolute terms for the Ku band than for the C band, while the standard deviation is always lower for the Ku band. This means that, although the Ku band chain performance is better than the one from C band, the Ku band ageing is faster than the one from C band, probably caused by the more stressed Ku band instrumental operations (e.g. bursts transmission & reception only in Ku band).

The PTR width standard deviation for the C band is around 6 times higher than the one from the Ku band, for both operational modes.

As a general observation, we can say that the behaviour of all calibration parameters is nominal. Nevertheless the different values shall be compared to the official S3 mission SRAL instrumental requirements in order to make a final statement. Once they are gathered, the calibration performance check versus requirements will be made, and warnings will be raised accordingly.

### 2.5 SRAL Dedicated Investigations

This chapter is devoted to the investigations derived from observations along the mission. The on-going investigations results will be updated in each new version of the report; solved issues will be dismissed from the report.

The flagging of some L1b CAL2 parameters (slope, mean and standard deviation over the slope) is reversed. This issue is not impacting the quality of the science data.

## 3 Calibration with Transponder

isardSAT has processed the TRP data from a list of L1A products The L1A from 2016 were reprocessed while the L1A products from 2017 are official products from PDGS centres.

The range bias results are of the order of millimetres. The datation bias is of the order of hundreds of microseconds.

The analysis has been completed for Cycles 3, 4, 6 to 9, 12 and 14 to 20.

Missing L2 products for cycles 5, 10 and 11 will be available with next reprocessing. Data before 15 June (cycles 4 and 5) will be available in a future reprocessing. The pass on cycle 21 (2017/08/08) is not considered because the transponder was not switched on due to high temperatures.

Table 3-1 and Figure 3-1 to Figure 3-4 present the results from the TRP passes processing. The range bias is computed as measured minus theoretical. The results show a positive measured range, 6.40 mm shorter than expected (elevation 6.40 mm larger than expected), and a datation bias of -156 microseconds, both extracted from the minimisation of the RMS between theoretical and measured series, and from the stack misalignment estimation. They also show a ~0.76 mm stack noise.

Table 3-1. Results of TRP passes processing

Regarding the geophysical corrections, the ionospheric and wet/dry tropospheric corrections were extracted from the transponder auxiliary files provided by the MPC team.

Then, the solid earth, geocentric tide and ocean loading corrections are selected from the L2 products. A table with the Geophysical corrections used is shown in Table 3-2. The TRP internal delay is 4.954 meters.
